

A. Prepregnancy underweight at different levels of local caste composition

At each tick on the x-axis, the sample of Adivasi, Dalit, and OBC women is restricted to women for whom the fraction of nearby households ranked higher in caste is less than or equal to that value. Prepregnancy underweight is then re-estimated using the reweighting method within the restricted sample. Confidence intervals are shown at selected cutoff values. For Forward caste women, this fraction is always zero by construction -- their estimate is shown as a horizontal reference line.

B. Distribution of share of nearby households that are higher ranking in caste

Nearby households refer to those in the woman's NFHS primary sampling unit. Households are determined as higher ranking than Adivasi or Dalit women if their household head is OBC. Households are determined as higher ranking than OBC women if their household head is forward caste.
